## **Why This Document Will Be Worth Your Time**

---

There are a growing number of tools through which users communicate and share information while they are at work or for work-related purposes:

- The average user in a smaller company (up to 500 employees) sends 48 emails on a typical day and receives 125; in larger companies, users send and receive 39 and 121 emails, respectively.
- Depending on the size of the company, 20% to 25% of emails contain attachments, any of which can contain confidential information.
- Webmail is used by 13% of users (in large companies) to 28% (in small companies).
- 31% of users in smaller companies and 16% of those in larger ones use Facebook; the figures for Twitter are 23% and 11%, respectively, and the numbers are growing.
- Consumer instant messaging clients are used by 15% of users (large companies) to 29% (small companies).

Now, consider that most of these messages and files are sent and stored without any sort of monitoring, encryption, inspection or oversight. The result is that organizations are deploying (or at least allowing) communications from a growing array of tools. And, at the same time, they are creating a growing number of opportunities for information to leak out of an enterprise in unauthorized and potentially damaging ways.

There are many well-publicized (and some not-so-well publicized) examples of sensitive data that has been sent through email and other tools in an authorized or mistaken manner. The vast majority of these data breaches are inadvertent, but the opportunity exists for malicious users to send confidential and sensitive data, as well.

### **DATA BREACHES CAN BE VERY SERIOUS**

The consequences of a data breach can vary widely: a confidential memo sent by a senior manager to the wrong client may carry with it no negative ramifications; the client may simply delete the email and the breach will simply be forgotten. However, data breaches can carry with them very serious consequences, such as the revelation in December 2009 that a hacker claimed to have access to account information for 32 million individuals in the RockYou database<sup>1</sup>. A 2009 study by the Ponemon Institute found that the loss of customer records costs \$204 per record, and that the average business loss for a large organization that suffers a data breach is \$6.75 million<sup>2</sup>.

The bottom line is that organizations must implement Data Loss Prevention (DLP) systems to protect themselves against the growing array of threats they face from inadvertent and malicious data leaks.

## **ABOUT THIS WHITE PAPER**

This white paper is an update to a white paper that Osterman Research published on DLP issues in 2008. It is sponsored by Blue Coat Systems – information on the company is provided at the end of this document.

## **DLP is Becoming Much More Important**

---

### **MANY ARE UNAWARE OF THE PROBLEMS WITH DATA LOSS**

According to a survey conducted by Osterman Research during May 2010, virtually 100% of organizations have deployed anti-virus and anti-spam capabilities. However, even using a fairly broad interpretation of data loss prevention (DLP) capabilities, which would include products that don't provide *true* DLP functionality, far fewer organizations have deployed such a capability.

Clearly, this suggests that organizations of all sizes are well aware of the need to monitor their inbound communications for spam and malware. However, they are not nearly as aware of the need to monitor outbound communications, or they are not taking the threat as seriously as they should. This, despite the fact that during the period May 2009 to May 2010<sup>3</sup>:

- 23% of organizations reported that sensitive or confidential information was accidentally or maliciously leaked through email.
- 9% reported that sensitive or confidential information was accidentally or maliciously leaked through a social networking or Web 2.0 application.
- 5% reported that sensitive or confidential information was accidentally or maliciously leaked through an instant messaging client.

### **BREACHES ARE BECOMING MORE NUMEROUS AND SERIOUS**

Data breaches are becoming more numerous and more serious. For example, the Privacy Rights Clearinghouse has tracked data breaches since early 2005 and has recorded many examples in which data breaches were caused by emails sent mistakenly; cases in which laptops, CD-ROMs and backup tapes with confidential data were lost or stolen; employees discarding printed content in dumpsters or at the curb for trash pickup; and many other instances in which sensitive data was compromised.

There are many risks that organizations know about and often do not address, such as employees who use corporate email systems in violation of stated policies or who use personal Webmail accounts to send company data home or when they want to send files that are larger than the corporate email system will allow. For example, a May 2010 Osterman Research survey found that 64% of organization allow employees to use personal Webmail while at work (up from 47% in 2007). There are also a variety of unknown risks, such as keystroke loggers that can infect corporate computers and distribute confidential data to hackers and others. These can often enter an

---

<sup>3</sup> Source: *Messaging and Web Security Market Trends, 2010-2013*

organization through personal Webmail accounts, one of the primary threat vectors with which organizations must contend.

It is also important to distinguish between authorized and unauthorized data breaches. For example, an employee who is authorized to place information on a company Web site or a corporate wiki can mistakenly post confidential information. By contrast, a terminated employee who is no longer authorized to send email can still use the system to send trade secrets to competitors or others until their access credentials are removed. Whether inadvertent (the vast majority of data breaches) or intentional, the damage caused by such breaches can be enormous.

### **MULTIPLE VENUES THROUGH WHICH DATA LOSS OCCURS**

There are many tools and systems from which confidential or sensitive information can be sent in violation of corporate policy:

- Corporate email systems used on desktops, laptops, mobile devices and home computers. Regarding the last venue, an Osterman Research survey<sup>4</sup> published in September 2009 found that 78% of employees check their work-related email from home on weekends, and slightly more check their work email from home after-hours on weekdays.
- Consumer and enterprise instant messaging systems.
- Personal Webmail accounts used at work.
- Thumbdrives and other portable storage devices.
- Social networking tools like Facebook, Twitter and LinkedIn.
- Other Web 2.0 applications, including wikis and blogs.
- File transfer protocol (FTP) tools.
- Chat tools.
- Skype and other consumer-oriented VoIP tools.
- Peer-to-peer file-sharing tools.
- Message boards and forums.

Further, there is a growing body of data-stealing malware that can result in substantial data loss. For example, the Zeus botnet malware, thought to have been developed and owned by a single individual in Eastern Europe, can be used to take control of remote PCs for the purpose of transferring funds out of financial accounts. The malware can be

---

<sup>4</sup> *Results of an End-User Survey on the Use of Communications Tools*, Osterman Research, Inc.

purchased for less than \$5,000 and is designed for high-value transactions – typically on the order of \$100,000 or more.

As a result, there are many protocols that organizations must monitor closely in order to protect corporate data from accidental or unauthorized distribution, although email and instant messages are clearly the most important channels to monitor given their pervasive and much more frequent use by employees than most other tools.

### **WHAT ABOUT DATA LEAKS THAT ARE JUST WAITING TO HAPPEN?**

The increasing use of content repositories and databases like Microsoft SharePoint, Lotus Quickr, Oracle, SAP and others – as well as file servers and FTP servers scattered around an organization – can create another, potentially significant, leak point for sensitive data. Confidential information is often stored in these locations for use by a group of users for an individual project or on an ongoing basis. Quite often, access to this content is uncontrolled, allowing anyone to view or download sensitive information, sometimes years later.

Fairly often, a DLP solution will be used in a discovery role for the process of scanning resources across the network to locate sensitive information in places it should not have been stored. In one case, a spreadsheet produced by a third party that contained the names, salaries, addresses, Social Security numbers, telephone numbers and their spouses' telephone numbers was discovered in an unprotected storage area that had been used for an audit of a hospital. Upon conclusion of the audit, the data should have been deleted or moved to a secure area but was not. A consultant was later given access to the same work area and found the spreadsheet. Unfortunately, this type of potential breach is a common occurrence.

### **PROBLEMS CAUSED BY NOT ADDRESSING THE DLP ISSUE**

Data breaches can be *very* expensive: for example, an Osterman Research survey found that if a data breach were to occur in which disclosure of the breach would have to be made to customers and other external contacts, nearly two-thirds of organizations estimated that a single such breach would cost their organization at least \$100,000, not to mention other operational costs, damage to their brand and other problems.

Organizations that do not properly address DLP can suffer a variety of problems, including:

- **Loss of intellectual property**  
Email systems, file transfer systems, instant messaging systems, blogs, wikis, Web tools, thumbdrives and other tools can be used to send confidential information in violation of corporate policy, common sense and the law. The result is that trade secrets, designs, proprietary processes and other knowledge assets can all be compromised if not adequately protected. For example:
  - Someone at the Office of the State Superintendent of Education in Washington, DC, which manages requests for college financial aid, mistakenly emailed personal information about 2,400 applicants to more than 1,000 of these

applicants in May 2009. The sensitive content was contained in a Microsoft Excel spreadsheet that was mistakenly attached to the email<sup>5</sup>.

- Walgreens Health Initiative (WHI) manages the pharmacy benefit of the Kentucky Retirement Systems (KRS). In March 2009, the pharmacy provider emailed 28,000 KRS members' records to the KRS benefits office without applying WHI's usual encryption process. In its disclosure letter, which is posted on the KRS website, WHI says the file was addressed only to a single and proper contact at KRS, and that the receipt of the file had been confirmed. The letter adds: "While there is a remote possibility that these records, containing limited personal information (name, date of birth, Health Insurance Claim [HIC] Number and Social Security number), were accessible while being transmitted, we believe the likelihood of any harm from this transmission to be very minimal."
- A British man in 2008 was forced to relinquish the mildenhall.com domain because he was constantly receiving sensitive emails that were mistakenly sent to his domain instead of to mildenhall.af.mil, the correct domain of the UK's Royal Air Force base at Mildenhall. The man had purchased the domain to promote the town, but told reporters that he had received numerous emails intended for the military base. These emails included the flight paths of Air Force One and President Bush, military tactics and passwords. The man worked with military officials to try to stop these emails, including blocking unrecognizable addresses, but the actions were unsuccessful<sup>6</sup>.
- In 2006, an employee of Duracell Corporation emailed confidential company information to a personal email account and then sent this information to two competing companies.
- In 2005, Oracle alleged that proprietary trade secrets had been posted by a former employee in a Google Groups posting.
- **Loss of reputation**  
If an electronic communication system is used in violation of corporate policy, an organization can suffer serious damage to its reputation. For example, the former CEO of Boeing, Harry Stonecipher, used the corporate email system to send personal emails to women with whom he was having extramarital affairs. His firing which resulted from this activity was highly publicized and embarrassing to the company.

In another well-publicized case, two employees of a North American bank sent a message via the corporate email system that depicted a photo of Senator Hillary Clinton's face superimposed on a nude body. The two employees were fired for violating corporate policy and filed a wrongful termination suit in response.

- **Harmful legal judgments**  
Unfettered use of email by employees can lead to significant and adverse legal judgments. For example, several years ago employees of British insurance company

---

<sup>5</sup> Source: Privacy Rights Clearinghouse

<sup>6</sup> <http://tinyurl.com/n4taby>

Norwich Union sent rumors using the corporate email system that falsely claimed that a competitor, Western Provident Association, was undergoing a government investigation and was experiencing financial problems. After Western Provident filed suit, Norwich Union publicly apologized for its employees' behavior and paid a judgment of £450,000 (~US\$780,000) in court costs and damages.

Because recent court decisions have clarified what organizations must do with regard to DLP, and because regulations are becoming more stringent, the consequence of data loss is much less of a gray area than it was even just a few years ago.

- **Compromise of corporate security**

A failure to properly monitor outbound communications can lead to a variety of security-related problems, including compromised PCs acting as zombies for sending spam and consumer instant messaging clients that can spread worms and malware. There are a variety of tools commonly used in the workplace that bypass conventional security defenses, including Skype, peer-to-peer file-sharing software and chat tools.

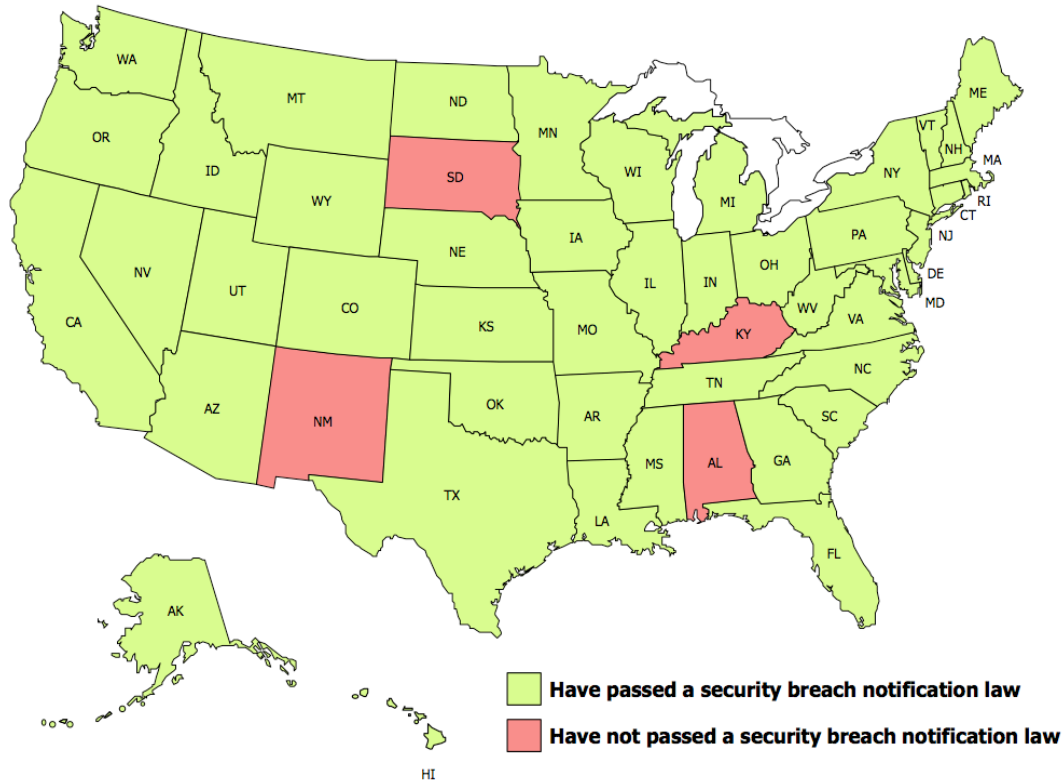

- **Violation of statutes and compliance requirements**

By not adequately monitoring and managing outbound content, organizations can run afoul of a wide variety of statutes that require data to be protected and retained. A small sampling of these statutes – but by no means an exhaustive list – include the following:

- California's SB1386 (the Database Security Breach Notification Act) is a far reaching law that requires any holder of personal information about a California resident to notify each resident whose information may have been compromised in some way. This requirement makes it very important to retain and transmit records in an encrypted form, since doing so exempts an organization from the reporting requirement in the event of a breach.

Since California passed its groundbreaking data breach notification law, most other US states have passed similar laws, as shown in the following figure. For example, Nevada put into effect a law (NRS 597.970) on October 1, 2008 that states, "a business in this State shall not transfer any personal information of a customer through an electronic transmission other than a facsimile to a person outside of the secure system of the business unless the business uses encryption to ensure the security of electronic transmission." Massachusetts has passed a similar, but more restrictive law that went into effect in 2010. While the Nevada law focuses on electronic transmission of information, the Massachusetts law focuses on the portability of data. That means that any personally identifiable information data an entity has on a Massachusetts resident that is stored on a laptop, mobile device, thumbdrive, etc. must be encrypted.

### Status of Data Breach Notification Laws in the United States

Data Source: National Conference of State Legislatures

- The Health Insurance Portability and Accountability Act (HIPAA) requires that Protected Health Information (PHI), such as an employee’s identity and his or her health condition or medications, remain confidential. For example, if an email that contains PHI is sent from a supervisor to an external benefits administrator, it must be encrypted. There are a variety of areas within HIPAA that must be addressed, including archiving of data, but protection of patient confidentiality is of paramount importance for all electronic communication.
- The Financial Industry Regulatory Authority (FINRA) Rule 3010 requires that relevant securities dealers’ correspondence with the public must be supervised, reviewed and retained. The goal of FINRA 3010 is to ensure that registered representatives are not making inappropriate claims to their customers, such as sending an email to a customer that guarantees that a stock will increase in value.
- The Gramm-Leach-Bliley Act (GLBA) requires financial institutions that hold personal information to transmit and store this information in such a way that its integrity is not compromised. GLBA requires financial institutions to comply with a variety of Securities and Exchange Commission and NASD rules.

- The Payment Card Industry Data Security Standard (PCI DSS) encompasses a set of requirements for protecting the security of consumers' and others' payment account information. It includes provisions for building and maintaining a secure network, encrypting cardholder data when it is sent over public networks and assigning unique IDs to each individual that has access to cardholder information.
- The Personal Information Protection and Electronic Documents Act (PIPEDA) is a Canadian privacy law that applies to all companies operating in Canada. Like many other privacy laws, it requires that personal information be stored and transmitted securely.
- The UK Data Protection Act imposes requirements on businesses operating in the United Kingdom to protect the security of personal information and to preserve information only as long as it necessary to do so. The Act requires, at least by implication, requirements for encrypted transmission of personal information and its secure retention.
- The UK's Information Commissioner issued The Employment Practices Data Protection Code in June 2005 which includes, among other things, limits on the extent to which employee communication can be monitored.
- Japan's Personal Data Protection Law is designed to protect consumers' and employees' personal information. It includes provisions for ensuring the security and disclosure of databases that contain this information, among other provisions.

It is important to note that the regulations identified above represent only a limited set of regulations and that it is important to view regulations at a variety of levels: geographically (state/provincial, Federal and global) and by industry sector. For example, some industries, such as some sectors of the financial services industry like broker-dealers, hedge fund managers and investment advisors, have specific requirements to which they must adhere. Some regulations, however, are cross industry and apply more generally, such as California's SB1386.

### **OTHER PROBLEMS ABOUND**

There are a variety of additional risks and problems that organizations face if they do not properly monitor outbound communications from email and other systems. For example, employees who send sexually harassing, racist or other offensive content can put an organization at significant risk:

- In a well-publicized case, Chevron Oil settled a sexual harassment lawsuit for \$2.2 million after four women received offensive email from a fellow employee.
- Morgan Stanley settled a \$60 million lawsuit filed by two employees after they received racist jokes sent through the company's email system.

### ***Why Your Organization Needs to Implement DLP***

- Citing Title VII of the Civil Rights Act of 1964 and the New Jersey Law Against Discrimination, the New Jersey Supreme Court ruled that an employer can be liable for materials posted by its employees on electronic bulletin boards.

Making the issue more difficult is that laws, policies and best practices for monitoring various systems differ widely by geography. For example:

- Laws in Germany and France make it more difficult to monitor employees' email use than in the United States.
- New Zealand's Privacy Act 1993, on the other hand, allows an employer to monitor its employees' communication if it has clearly informed them it will do so.
- A 2003 report by Sweden's Data Protection Authority concluded that employers must obtain the voluntary consent of employees in order to monitor their communication.

While some of the statutes noted above focus largely on archiving, e-discovery or reporting requirements and not monitoring per se, there is an implied need to monitor outbound communications for potential data breaches. For example, while SB1386 requires an organization only to *report* breaches of data for California residents, organizations that hold this data should *monitor* their outbound content to prevent these breaches.

In short, data breaches and the unmonitored use of electronic communication tools can be very damaging to an organization of any size and can lead to loss of reputation, revenue, and customers; and can create substantial regulatory and legal risk.

### **WHY ISN'T DLP MORE WIDELY DEPLOYED?**

One of the reasons that organizations have not yet deployed DLP systems can be explained by the fact that many decision makers are not aware of the potential risks they face, nor might they be aware of the data breach examples among organizations similar to their own. For example:

- Employees will often accidentally send confidential data in an email – such as credit card numbers, Social Security numbers or other confidential information – without realizing that the data needs to be encrypted during transmission.
- There are many cases in which confidential data, unbeknownst to the sender, is buried in an email thread that is forwarded to others.
- Email is sometimes sent email to the wrong person, often resulting in the leak of confidential information.
- Some employees will send confidential data via personal Webmail accounts to others or to themselves to avoid file size limitations on attachments or so that they can work on documents at home.

- Web 2.0 applications represent a significant potential for data loss. For example, Twitter, Facebook and other social networking sites can be used to share data, often inadvertently, in violation of the law or corporate policies.
- Online applications can also be used to share data, such as posting data using an online calendar that could reveal sensitive or confidential information.

Another reason for the low penetration of DLP technologies is that many decision makers view DLP as a complicated set of technologies that takes a long time to deploy. And, historically speaking, these decision makers are right – DLP systems in the past have been complicated and have required months to deploy. However, DLP solutions are maturing and today are much less complicated and much faster to implement. For example, some solutions can be up and running in as little as eight hours. The onus, then, is on vendors to educate decision makers about the advances that have occurred in DLP over the past few years.

## What Should You Do?

---

### **STEP 1: UNDERSTAND JUST HOW SERIOUS THE PROBLEM IS**

The first step that decision makers should take to solve the data breach problem is to audit the current state of electronic communication and file management in the organization. Doing so will reveal the extent of the risks that an organization faces and will help to make real the problem to IT management, as well as senior line-of-business decision makers. In many cases, this will help an organization to realize that the risks and problems it faces are not merely a potential, theoretical problem, but are instead a real and present business danger that it must address. While this is not always a necessary step given the abundance of evidence that exists for the data breach problem, it may be required by some organizations in order to convince senior managers of the extent of their own organization's problems.

Audits of communication and file management tools can be conducted in a variety of ways. For example:

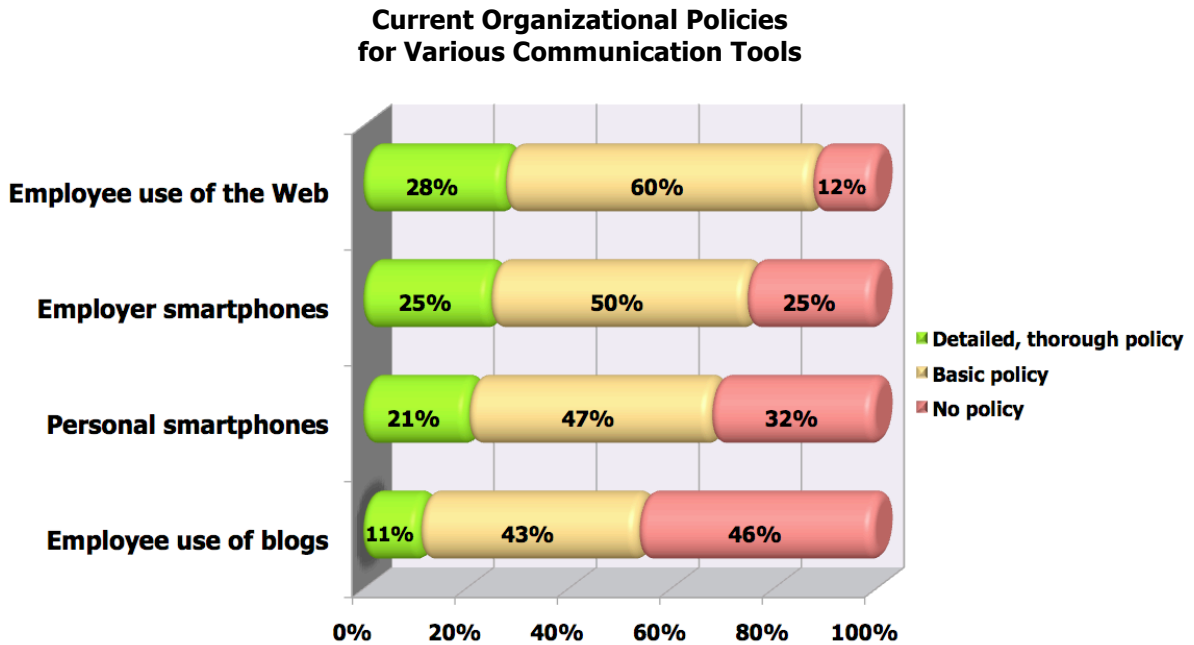

- Networking monitoring tools can be used to scan email communication using the corporate email system, personal Webmail, instant messages, social networking posts, blog posts and other employee communications. Searches can then be conducted on this content to look for credit card numbers, Social Security numbers, emails that are sent to competitors' domains, specific violations of statutes or corporate policies and other information.
- Another method is to draw a random sample of communications, such as emails sent using the corporate email system or employees' emails sent using Webmail systems, and then search the content for similar types of information.

The purpose of such an audit is to identify and to quantify the problem of unmanaged communication so that senior management, legal counsel, HR and others can understand the extent of the risk the organization faces. It may also help IT managers

to garner budget (or additional budget) for their DLP initiatives relative to other, competing initiatives.

## STEP 2: ESTABLISH POLICIES FOCUSED ON STOPPING BREACHES

After the audit has been completed and digested by senior managers, an organization should establish very detailed and thorough corporate policies that focus on all of the issues related to the use of electronic communication and file management capabilities. This is clearly something that most organizations have not yet done, as shown in the following figure<sup>7</sup>:

The policies that organizations develop should include:

- An emphasis on DLP as part of an overall objective to protect against data loss, not just a set of “bolt-on” technologies that can be added after the fact. This requires a higher level solution set, including firewalls, anti-malware protection, blocking access to ports that could be used as egress points for unmanaged content, etc. In short, consider data loss as a threat to the organization, but view data loss in the context of everything an organization does with regard to security.
- Appropriate and inappropriate use of email by employees and what constitutes inappropriate use. This should include not only the content of emails, but also parties to whom email should not be sent, the types of content that should be encrypted, how email should be used on mobile devices, whether or not email should be checked from home, and so forth.

<sup>7</sup> Source: *Messaging Policy Market Trends, 2009-2012*, Osterman Research, Inc.

- The extent to which corporate systems may be employed for personal use.
- Use of personal Webmail accounts over company-owned networks and/or use of these accounts during work hours. This is a particularly important component of any security policy, since Webmail accounts for one of the more serious threat vectors in any organization
- The types of information that should be sent through various media. For example, a company may want to establish a policy that allows attachments to be sent only through email and not instant messaging systems, or that requires attachments containing certain content to be encrypted or sent through an attachment management system.
- The types of communications that constitute business records, how long business records should be preserved, and when and how they should be deleted.
- Limits on the type of tools that may be used. For example, a company may want to prevent the installation and use of consumer-oriented instant messaging clients, or it may want to limit use only to a particular client.
- Organizations must understand any regulations that govern monitoring polices, particularly in countries that place restrictions on how monitoring practices may be carried out.

Further, corporate policies should include provisions that will set employee expectations about the use of electronic communication tools. For example, part of any corporate policy should include a statement that some types of electronic communication do not provide guaranteed delivery of content. This is important not only to protect organizations from the consequences of improper employee behavior, but can also serve as a guide to delivery of time-sensitive communications.

### **STEP 3: DEPLOY THE RIGHT TOOLS**

The critical next step is to deploy the technologies that will enforce the corporate policies that have been established. While policies are necessary to establish what an organization needs to protect, they will be ineffective at solving all of the data breach problems an organization might experience.

Any system that an organization deploys should:

- **Identify the leak points**  
Focus on the potential leak points. This includes not only IT-deployed tools like the corporate email system, but also things like Webmail that represents one of the biggest gaps in DLP defenses.
- **Include capabilities to meet current and future requirements**  
It is important to deploy a technology that will meet the large and growing number of potential data leaks an organization might encounter. This includes inspecting for file metadata, industry-specific keywords and phrases, regular expressions (e.g.,

email addresses), exact file matches and performing statistical analysis to detect specific types of content, such as employee resumes sent out through email.

- **Deploy systems that will take appropriate action**

Based on the suspected level of data breach, the systems that monitor outbound communication should take the appropriate action. For example, an employees' instant message that contains what looks like a Social Security number may warrant nothing more than a popup window on the sender's display that reminds them of a corporate policy against sending this information through an instant messaging client. On the other hand, an email that contains an attachment with proprietary information sent through an employee's personal Webmail account may warrant immediate redirection of the message to a compliance officer or supervisor for further review before the message is sent. In short, suspected data breaches should trigger only the appropriate actions of discarding messages, quarantining them for further review, copying them to a supervisor, requiring encryption, archiving them, etc.

Incident management is a key component of any system, since each suspected data breach should be handled with the right level of enforcement. For example, in a large organization it would be impractical to route every suspect email to a compliance officer or supervisor for review.

- **Promote appropriate employee handling of data**

For example, if an employee sends an inappropriate message to a co-worker or a confidential document to a competitor's domain, a monitoring system should remind employees of corporate policies that may exist regarding the appropriateness of the communications vehicle they have chosen or other corporate policies. Copying of sensitive documents to removable storage devices should be monitored because of the high risk of data loss from these devices. Osterman Research surveys have found overwhelmingly that decision makers want to provide reminders and other "soft" types of enforcement rather than routinely sending potentially offending messages to compliance officers, supervisors or HR.

- **Perform the appropriate level of inspection**

Based on corporate policies, the role of the employee in the organization and other factors, content should be inspected based on the appropriate policies. For example, certain employees may require different levels of outbound content inspection and data retention than others – a broker/dealer's email to a client may trigger a different set of policies compared to a clerical staff member's email to the same client. Certain recipients of an email may trigger different policies based on the company's history with those recipients. A CEO's email to an external auditor should trigger different inspection and retention requirements than those triggered by a marketing staff member's email.

It is important to expend the appropriate level of computing resources necessary to satisfy corporate and other policies in order to maximize the performance of electronic communication and management systems. For example, performing deep content inspection on every message that flows through the network is simply not

necessary in many cases. However, inspecting content flowing through key threat vectors, such as removable storage or encrypted Webmail channels, is critical.

- **Train and make employees aware of corporate policies**  
Employees should receive regular training on corporate policies and good data management practices and should continually be made aware of appropriate ways to send information.
- **Implement forensics capabilities**  
Organizations may want to implement forensics capabilities in order to check on how data has been handled after it has been sent, either for legal purposes or simply to understand how its data is being managed. The ability to learn about how outbound content was sent and processed is just as important in many cases as monitoring this content prior to its being sent. It is also useful to retain copies of actual email, attachments, or files being copied to USB devices.
- **Implement a sender authentication scheme**  
While not an outbound content scanning mechanism, it is important for any organization to implement an authentication mechanism, such as SPF or DKIM, to ensure that recipients of its emails are given some level of assurance that the sending organization is valid.
- **Tight integration with existing infrastructure**  
In order to speed reduce costs, organizations should consider solutions that are well integrated with their IT infrastructure whenever possible. This approach will also speed implementation and lower on-going administration costs.

### **WHAT WILL ORGANIZATIONS DO?**

Osterman Research believes that most organizations are waking up to the fact that they need to implement DLP capabilities. For example, an Osterman Research survey conducted in May 2010<sup>8</sup> found that:

- 41% of mid-sized and large organizations will very likely or definitely invest in DLP systems during the next 12 months.
- 42% will very likely or definitely invest in technology to monitor outbound social networking posts, such as posts to Twitter, Facebook, etc.
- 56% will very likely or definitely invest in systems to manage or control Web access.

---

<sup>8</sup> Source: *Messaging and Web Security Market Trends, 2010-2013*, Osterman Research, Inc.

## Summary

---

Outbound content sent from any communications tools or stored on laptops and removable storage devices must be monitored and managed in order to minimize risk and to ensure that the content is appropriate and in compliance with an organization's policies, statutory obligations and industry best practices. Organizations should monitor all avenues through which employees may communicate, including email, instant messaging systems, wikis, blogs, personal Webmail accounts, USB devices, message boards and other tools. The appropriate policies should be established and systems should be deployed so that an organization's risk can be mitigated to the extent possible.

## Sponsor of this White Paper

---

**Blue Coat Systems**  
**420 N. Mary Avenue**  
**Sunnyvale, CA 94085**  
**+1 866 302 2628**  
**[www.bluecoat.com](http://www.bluecoat.com)**

Blue Coat Systems, Inc., founded in 1996, (NASDAQ: BCSI) is a publicly held company based in Sunnyvale, California. Blue Coat secures Web communications and accelerates business applications across the distributed enterprise. Blue Coat's family of appliances and client-based solutions – deployed in branch offices, Internet gateways, end points, and data centers – provide intelligent points of policy-based control enabling IT organizations to optimize

security and accelerate performance for all users and applications. Blue Coat has installed more than 8,000 customers worldwide and is ranked #1 by IDC in the Secure Content and Application Delivery market.

Blue Coat appliances and software technology help IT organizations secure Web communications and accelerate delivery of business applications for all users across the distributed enterprise - including Internet gateways, branch offices, data centers, and even individual end points. Blue Coat appliances function as intelligent points of control wherever users and applications are connected to the network, and provide these important capabilities.
